Abstract

The sorption of cadmium (II) on chitosan has been found to be dependent on contact time, concentration, temperature, and pH of the solution. The process of removal follows first order kinetics and absorption of heat.

Keywords: Chitosan, bioabsorbent, cadmium (II), heavy metal adsorption, chitin.

Introduction

The general methods of treating wastewater having cadmium follow precipitation and ion exchange ¹. Recently, much interest has been exhibited in the use of sorption technique for the removal of cadmium from wastewater using chitosan. The present investigation aims at using chitosan, a low cost and highly effective sorbent for the removal of cadmium from waste water. Chitosan is a biopolymer, which is extracted from crustacean shells or from fungal biomass ². The structure of chitosan is presented schematically in figure 1.

Material and Methods

Experimental Procedure: Chitosan was obtained from India sea foods, cochi India. Batch sorption experiments were carried out in temperature controlled shaking machine by agitating 25ml aqueous solutions of sorbates with 1.0 g sorbent in different glass bottles at different conditions of concentrations, temperatures and pH. The pH of different solutions was adjusted with 0.05 M NaOH or HCl by pH meter, systronic 335. The speed of agitation was maintained at 1000 rpm to ensure equal mixing. The progress of sorption was noted after each 20 min till saturation. At the end of predetermined time interval each 20 min, the sorbate and sorbent were separated by centrifugation at 16,000 rpm and the supernatant liquid analyzed by atomic absorption spectrophotometer.

Results and Discussion

Effect of Contact Time and Concentration: The removal of Cd (II) by sorption on chitosan from aqueous solution increase with time (figure-2) till equilibrium is attained in 140 min. The figure show that time of saturation is independent of concentration. It is further noted that the amount of cd (II) sorbed increases from 1.913 mg.g-1 to 3.764 mg.g-1 by increasing cd (II) concentration from 100 mg/l to 250 mg/l. the time-amount sorbed curve is single, smooth and continuous indicating monolayer coverage of cd (II) on the outer surface of chitosan ³.

Keywords: Chitosan, bioabsorbent, cadmium (II), heavy metal adsorption, chitin.

Figure-2

effect of concentration for the sorption of cadmium (II) on chitosan;
● 100 mg/L, ● 150 mg/ L, ● 200 mg/L, ● 250 mg/L
**Sorption Kinetics:** The kinetics of sorption of cd (II) on chitosan was studied using Lagergren equation

\[
\log (q_e - q) = \log q_e - \frac{kt}{2.3} \quad (1)
\]

Where \(q_e\) and \(q\) are the amount sorbed (mg.g\(^{-1}\)) of cd (II) at equilibrium and at time \(t\) respectively and \(k\) is sorption constant. The straight lines obtained from the plots of \(\log (q_e - q)\) against \(t\) (figure-3) and different concentrations indicate that the sorption process follows first order kinetics.

**Effect of temperature:** The amount of cd (II) sorbed on chitosan increases from 1.913 mg.g\(^{-1}\) to 2.249 mg.g\(^{-1}\) by increasing temperature from 30\(^\circ\)C to 40\(^\circ\)C indicating the process to be endothermic (figure- 4).

**Langmuir isotherm:** The equilibrium data at the different temperatures follow Langmuir equation

\[
\frac{C_e}{q_e} = \frac{1}{\phi \cdot b} + \frac{C_e}{\phi} \quad (2)
\]

Where \(C_e\) mg.L\(^{-1}\) is equilibrium concentration of cd (II) and \(\phi\) and \(b\) are Langmuir constants related to sorption capacity and sorption energy respectively. The value of \(\phi\) and \(b\) (table 4) were determined from the slope and intercept of linear plots Fig. 5. The sorption capacity also increases with 0 temperature suggesting that the active centers available for sorption have increased with temperature.

The change in free energy (\(\Delta G^\circ\)), enthalpy (\(\Delta H^\circ\)), and entropy (\(\Delta S^\circ\)) of sorption have been calculated using following equations,

\[
\Delta G^\circ = -RT \ln K \quad (3)
\]

\[
\Delta H^\circ = RT \ln \frac{k_2}{k_1} \quad (4)
\]

\[
\Delta S^\circ = \frac{\Delta H^\circ - \Delta G^\circ}{T_1} \quad (5)
\]

Where \(K_1\) and \(K_2\) are equilibrium constants at temperature \(T_1\) and \(T_2\) respectively.

The negative values of \(\Delta G^\circ\) (table 2) indicate the spontaneous nature of the sorption process. The positive values of \(\Delta H^\circ\) at different temperature support the endothermic nature of the process.

**Effect of pH:** The amount of Cd (II) sorbed on chitosan increases from 1.990 mg.g\(^{-1}\) (79.6 %) to 2.330 mg.g\(^{-1}\) (93.2 %)
by increasing pH of the solution from 2.0 to 6.5 (Fig. 5). The Sorption capacity $\Phi$, also increase with the increase of pH.

### Conclusion

From the above discussion it is clear that due to chemical composition, structure, more adsorption sites, cheap, availability in plenty etc. this substance will provide to be efficient adsorbent.

### Acknowledgement

The authors are thankful to Dr. Nagesh Gaveli, Director, Sudarshan College of science, management and research, Pune (Maharashtra), for providing research facilities, co-operation and constant encouragement to carry out the work.
